BETA (DRAFT)

Introduction

The ACTDiag Diagnostics utility is a program installed with Sage ACT! Pro and Sage ACT! Premium 2012.

Note: When features are exclusive to Sage ACT! Premium, they are noted in the guide. In most sections, we refer to both versions as Sage ACT!.

ACTDiag can be used to repair and maintain Sage ACT! databases and to manage some aspects of the local Microsoft® SQL Server® instance for Sage ACT!. ACTDiag only works on the local machine. You cannot connect to remote SQL Server machine instances. Since this utility primarily provides low-level physical diagnostic and corrective actions against the SQL Server instance and its databases, most features and tasks do not require a user logon to the Sage ACT! Framework or application. If you need assistance using ACTDiag, contact Sage ACT! Technical Support at www.act.com/support.

This document describes:

- The ACTDiag utility interface.
- The tasks you can perform relating to the SQL Server instance for Sage ACT!, including how to stop and start the SQL Server instance for Sage ACT!.
- The tasks you can perform relating to the database, such as maintaining and rebuilding databases, including adjusting performance.
- Reports and event logging available through the ACTDiag.

Using the ACTDiag Utility

By default, the ACTDiag.exe is installed to the same directory as the Sage ACT! application. You can create a shortcut on the desktop for easier access to the ACTDiag utility. You can also add the ACTDiag.exe to the Sage ACT! application's toolbar as a custom command. See Help in Sage ACT! for how to add custom commands to toolbars.

Opening ACTDiag

The following steps explain one way to open ACTDiag. If you are using Windows Vista® or Windows® 7, you may have to access ACTDiag using the "Run as administrator" command. See Windows Vista or Windows 7 Help for more information.

Open the ACTDiag utility

1. Open the Windows **Run** dialog box.
2. In the **Open** field, type **Actdiag.exe**.
3. Click **OK**.

ACTDiag opens to the Server Information page. More about this page is described in later sections of this guide. The following section describes the ACTDiag menus.

About the ACTDiag Utility Menu Commands

In ACTDiag, the following menu commands are available.

File. Close ACTDiag using the Exit command.

Server. Provides commands to manage the local SQLServer instance for Sage ACT!.

Databases. Opens the Database List, Database Settings, and Audit Logs commands.

Actions. Available only when you are in the Databases List view. Use the Database List command to open the view. The commands on the Actions menu let you perform database maintenance, run database reports, and rebuild databases.

Tools. Provides additional database maintenance commands.

Help. - Opens this guide and accesses the About ACTDiag Diagnostics page. The About ACTDiag page provides program and vendor information and a link to the Sage Technical Support Web site.

The following items are also provided on the About ACTDiag Diagnostics page.

Version. This may or may not match the version of your Sage ACT! application; either is acceptable.

Command Timeout (seconds). Displays the number of seconds an ACTDiag task or action can take before stopping on its own. By default, this is 600 seconds (10 minutes). You may need to increase the time for slower machines or if you have a very large database. If you receive timeout errors, close ACTDiag, open the ACTDiag.exe.config file with Notepad, and then increase the CommandTimeout.Default value:

```
<add key="CommandTimeout.Default" value="600"/>
```

Managing the SQL Server Instance for Sage ACT!

The Sage ACT! installation program creates a named, local SQL Server instance called ACT7. The ACTDiag utility Server menu contains commands that let you view that SQL Server instance for Sage ACT! and manage it, with limitations.

The Server menu commands include:

- Server Information
- Server Security
- Server Settings
- SQL Error Logs
- SQL Diagnostics
- SQL Connections

The following sections explain the Server menu commands and tasks you can perform using those commands as well as how to stop and start the SQL Server instance for Sage ACT!.

Viewing the SQL Server Instance Information for Sage ACT!

When you select the Server Information command, the page displays pertinent local SQL Server instance properties for Sage ACT!. These properties include:

- Server name, edition, and version (typically including the Service Pack level).
- Collation details (language and sorting).
- Service account (the Windows account context under which the SQL Server instance for ACTDiag is registered and runs).
- Connection and date and time the service was started.
- Server options of CLR Enabled or CLR Disabled to indicate whether user assemblies can be run by SQL Server (assemblies are required for the ACT! OLEDB Provider 2.0).

Viewing and Specifying Security and Connectivity Settings

The Server Security command opens a page that lets you:

- Reset the SQL Server password.
- View and export SQL Server account actions.
- View and specify connectivity settings.

Resetting the SQL Server Password

You, as the machine user, can reset the local SQL Server password (sa). You cannot see the current SQL Server password or specify it.

Reset the SQL Server Password

1. Click **Server**, and then click **Server Security**.
2. Click **Reset SQL Password**.
3. At the Warning message, click **Yes** to reset the password and close all applications.

Viewing and Exporting SQL Server Account Actions

You can produce a report of actions taken to view, set, or reset the SQL Server login accounts, including the "sa" and "ActReader" accounts. The "sa" and "ActReader" accounts are available to Sage ACT! Premium and Sage ACT! Premium (access via web) users only.

View and export SQL Server account actions

1. Click **Server**, and then click **Server Security**.
2. Click **SQL Account Audit**.
3. To export the report to an XML file and save it to the desktop, click **Export**.

How the SQL Server Instance Works on a Local Area Network (LAN)

By default, when Sage ACT! installs the SQL Server instance, it is network-enabled; that is, it allows connection attempts from other machines. If this is not needed, you can disable network connections. For synchronization between databases, you do not need to network-enable the subscriber (child or remote) database and machine, but you must network-enable the machine(s) listening for synchronization requests and hosting the publisher (parent or main) database.

You can enable, disable, and configure your local SQL Server instance to participate on a Local Area Network (LAN) with other computers. You can also specify how client connections are made to other non-local SQL Server instances.

The two server-side components for configuring and allowing connections to the local SQL Server instance for Sage ACT! are:

- SQL Server (ACT7)
- SQL Server Browser

The SQL Server Browser program runs as a Windows service. SQL Server Browser listens for incoming requests for SQL Server resources and provides information about SQL Server instances installed on the computer, including the SQL Server instance for Sage ACT!.

Stopping the SQL Server Browser service disables the ability of the SQL Server instance for Sage ACT! (and any other installed SQL Server instances) to have other computers connect to it by machine and instance name. By default, the SQL Server Browser service is configured to start automatically.

Disallowing Connections From Other Computers

The following explains how to disallow connections to the SQL Server instance for Sage ACT! from other computers.

Disallow connections from other computers and assign a static port

1. Click **Server**, and then click **Server Security**.
2. Click **Server Configuration Manager**.
3. Expand the **SQL Server Network Configuration** item in the left pane. Select the **Protocols for ACT7** item.

The Protocol Name list appears in the right pane. By default, Shared Memory, TCP/IP, and Named Pipes are Enabled to allow connections from other computers.

4. To disallow connections from other computers:
 - a. Right-click **TCP/IP**. Select **Disable**.
 - b. Right-click **Named Pipes**. Select **Disable**.
5. To assign a static port:

- a. Double-click **TCP/IP** to open the TCP/IP Properties pane.
 - b. Click the **IP Addresses** tab.
 - c. Scroll down to the **IPAll** section. In **TCP Dynamic Ports**, enter **0**.
 - d. Under **TCP Port**, specify an available TCP port number. Click **OK**.
6. Stop and restart the SQL Server instance for Sage ACT!. For more information, see "[Stopping or Starting the SQL Server Instance for Sage ACT!](#)" on page 9.

Suppressing the Broadcast of the Local SQL Server Instance for Sage ACT!

By default, when a user browses the network for available SQL Server instances, the ACT7 instance is shown. You can suppress the broadcasting and listing of this SQL Server instance from other machines on the network.

Suppress the broadcast of the local SQL Server instance for Sage ACT!

1. Click **Server**, and then click **Server Security**.
2. Click **Server Configuration Manager**.
3. Expand the **SQL Server Network Configuration** item in the left pane.
4. Right-click the **Protocols for ACT7** item. Select **Properties**.
5. On the **Flags** tab, change the **Hide Instance** value to **Yes**.
6. Click **OK**.

Specifying Connectivity from the Sage ACT! Client to a SQL Server Database

The following explains how to specify a connection to a local or non-local database.

Specify connectivity from the Sage ACT! client to a SQL Server database

1. Click **Server**, and then click **Server Security**.
2. Click **Server Configuration Manager**.
3. Expand the **SQL Native Client Configuration** item in the left pane. Select the **Client Protocols** item.
4. To connect to a local database:
 - a. In the right pane, ensure the **Shared Memory** protocol is set to **Enabled**. If it is not, right-click it and select **Enable**.
 - b. Ensure the **Order** is set to **1**.
5. To connect to a non-local database:
 - a. Ensure the **TCP/IP** protocol is set to **Enabled**. If it is not, right-click it and select **Enable**. Ensure the **Order** is set to **2**.
 - b. Ensure the **Named Pipes** protocol is set to **Enabled**. If it is not, double-click it and select **Enable**. Ensure the **Order** is set to **3**.
6. Close the SQL Server Configuration Manager.

Changing Server Memory, Processor, and Database Warmup Settings

You can manage some aspects of how the SQL Server instance for Sage ACT! is configured to use memory and the processor on the local machine. By default, the SQL Server instance is configured to self-manage with no upper or lower memory limitations or boundaries. Also, the SQL Server instance is configured to use all available processors (as supported by the edition of SQL Server). Microsoft recommends these configuration settings. However, you can change these settings to accommodate requirements on each machine.

By default, the SQL Server instance for Sage ACT! is enabled to allow automatic database warmup. You can disable database warmup and change the default settings for it. Database warmup may help improve performance when logging on to a Sage ACT! database.

CAUTION: You should change these settings only when Sage Technical Support directs you to. These changes can affect performance of Sage ACT! and other applications running on the machine. The SQL Server Error Log records these changes. For more information, see "[Viewing SQL Server Error Logs](#)" on the facing page.

Configuring SQL Server Memory

You can configure SQL Server to dynamically adjust the amount of memory based on demand. You can use Minimum(MB) to guarantee a minimum amount of memory to SQL Server. Or, use Maximum(MB) to prevent SQL Server from using more than the specified amount of memory, thus leaving remaining memory available to run other applications.

General Guidelines.

- On non-server editions of Windows (such as Windows XP Professional or Windows Vista Home Premium), you might want to reduce the Maximum memory setting if many desktop applications are open simultaneously and Windows Task Manager shows a strain on available system memory.
- On server editions of Windows (such as Windows Server® 2003), you might want to increase the Minimum memory setting and leave the Maximum memory at the highest possible value if the SQL Server instance hosts many workgroup databases.

Configure SQL Server memory

1. Click **Server**, and then click **Server Settings**.
2. Click the **Server Memory** tab.
3. Move the sliders for **Minimum (MB)** or **Maximum (MB)** settings.
4. To save the changes, click **Apply**. To cancel or undo a change, click **Cancel**.

Specifying the Number of Server Processors

You can specify the number of processors to use for parallel execution of queries. By default, the option is set to use all available processors. For machines with hyper-threading, you should set this to the actual number of physical CPUs.

On single-CPU systems, no options are available on this page. You can run msinfo32 to view the number of physical processors (CPUs) for your machine.

General Guidelines.

- On most newer hyper-threaded CPUs, such as Intel® Pentium® 4 processors that are 2.7GHz and above, you should set the "Use n processor(s)" value to the number of actual physical CPUs installed in the machine. For example, the CPU Usage chart on the Performance tab of Windows Task Manager may show two graphs when only one physical CPU is installed.
- On most systems with non-hyper-threaded CPUs, you should leave the "Use all available processors" option selected.

Specify the number of processors

1. Click **Server**, and then click **Server Settings**.
2. Click the **Server Processor** tab.
3. Select the **Use n processor(s)** option and select or type a number.
4. To save the changes, click **Apply**. To cancel or undo a change, click **Cancel**.

Disabling Database Warmup or Changing Database Warmup Settings

By default, the Sage ACT! database you access most is enabled to warm up or get partially “pre-loaded” into memory. This is set to occur upon startup of the SQL Server database engine. This feature allows the initial logon to that database to be faster. To use database warmup, a database must reside on the same machine from which you run Sage ACT!.

With database warmup enabled, default values of three databases (if there are three databases attached to the SQL Server instance), and those accessed within the last 30 days, are also set. Each time a user accesses the database, Sage ACT! keeps track of the date and time that the database was accessed. If database warmup is disabled, the other database warmup settings are not active.

Note: Database warmup may cause additional resource consumption (by memory and CPU) during machine and SQL Server startup. The amount of impact depends upon the machine hardware, as well as configuration settings for the number of local databases and days prior. Setting the number of most recently accessed databases to a number higher than three, and/or the last number of days higher than thirty may cause a longer startup time for your machine.

Disable database warmup or change the default database warmup settings

1. Click **Server**, and then click **Server Settings**.
2. Click the **Database Warmup** tab.
3. To change the default settings, clear or type new values.
A value of zero (0) means no databases or no days. It does not mean "unlimited."
4. To save the changes, click **Apply**. To cancel or undo a change, click **Cancel**.

Viewing SQL Server Error Logs

You can view the error logs generated by the SQL Server. These logs record both system- and user-defined errors and events. They can help you diagnose problems related to SQL Server. Each event is recorded with a timestamp, and the logs are cycled each time the SQL Server service is started.

By default, SQL Server retains the current and last six error logs.

View a SQL Server error log

1. Click **Server**, and then click **SQL Error Logs**.
2. Click **View Logs**.
3. Select the log file to view. Click **Open**.

The current log file is named ERRORLOG; earlier log files have a numeric extension. The log details appear in the pane. Use the scroll bars to view the details.

4. To clear the view, click **Clear**.

Tip: You can also use Tools>Collect All ACT!-related Log Files to consolidate all Sage ACT!-related files, including the SQL Server error logs, into a compressed .zip file. For more information, see ["Performing Database Maintenance and Other Operational Tasks" on page 13](#).

Running SQL Server Diagnostic Tasks and Checking Permissions

You can perform diagnostic tasks specific to the SQL Server instance for Sage ACT!. The SQLDiag Snapshot and SQLDiag Monitor utilities, both of which invoke the Microsoft SQLDiag utility, can interrogate the SQL Server environment and configuration and the Windows and machine environment (similar to msinfo.exe).

You can also verify failed operations for permissions of the SQL Server instance to read and write to files or folders.

Running SQL Server Diagnostics

You can run two processes to capture system and SQL Server diagnostics and trace files.

SQLDiag Snapshot. Produces a full system and SQL Server diagnostic trace to a series of output files. You should run this process if you suspect problems or are directed to by Sage Technical Support. This process automatically stops the trace when done.

SQLDiag Monitor. Captures a system and SQL Server diagnostic trace. You should start this task prior to reproducing an error as directed by Sage Technical Support. You will need to stop the trace when done.

Note: You need the SQL Server "sa" password to capture the SQL Server diagnostics. If you do not enter a password, the process will only capture the system diagnostics.

Each process produces several text files containing information about the SQL Server configuration and environment, the machine, and the Windows operating system. The resulting files are placed on the Windows Desktop in a folder named: ACT!SQLDiag. You may be asked to supply this folder to Sage Technical Support to assist in diagnosing a problem.

Tip: If you experience an error when performing a certain action in Sage ACT!, and you can reproduce that error, start the SQLDiag Monitor task first. After reproducing the error, stop the SQLDiag Monitor task and follow the instructions.

Run SQL Server diagnostics

1. Click **Server**, and then click **SQL Diagnostics**.
2. Click **SQLDiag Snapshot** or **SQLDiag Monitor**.
3. Read message prompts. Click **Yes** or **OK** to continue.
If you click No or Cancel, the process is cancelled.
4. At the prompt, enter the SQL Server "sa" password.
5. To view the output folder of the results, click **Yes**.

Checking SQL Server Permissions

Some Sage ACT! tasks, such as saving a file with a different name or creating a remote database for database synchronization, require interaction between the SQL Server and files or folders in the Windows operating system. You can check and verify the permissions of the SQL Server instance for Sage ACT! to read and write to these files and folders. Test files and folders are created and deleted to verify SQL Server permissions.

Check SQL Server permissions

1. Click **Server**, and then click **SQL Diagnostics**.
2. Click **Check SQL Permissions**.
3. Select a folder. Click **Check**.

- a. Ensure that the **Environment Path** value includes the default system information.
- b. Ensure that each line in the **Permission Results** list displays **Successfully created** and **Successfully deleted** for the test file and folder.

If other results appear, you may have Windows permissions issues, or you may need to restart your system. A system restart is most likely if you are running VMware®. Contact Sage Technical Support if you continue to get other results.

Viewing SQL Server Connection Information

You can view the information for all connections to the local SQL Server instance for Sage ACT! in the SQL Connections grid. You can see the name of each computer, database, program, last activity, and more. However, the current connection used ACTDiag does not display in the grid.

View SQL Server connections

1. Click **Server**, and then click **SQL Connections**.
2. Click the **Refresh** button to refresh the connection information.

Stopping or Starting the SQL Server Instance for Sage ACT!

During installation, the local SQL Server instance for Sage ACT! is configured to start automatically when the Windows operating system starts. Running the local SQL Server instance is required to:

- Create a new database.
- Open and use a local database.
- Run ACT! E-mail and store POP3 account items locally.

If none of these scenarios apply, you can configure the Windows operating system to skip starting the SQL Server instance for Sage ACT! on start-up. This can improve overall system performance by using less memory and resources.

There are several ways to stop or start the local SQL Server instance for Sage ACT!:

- On the **Tools** menu, point to **Stop/Start SQL Service**, and then select **Start** or **Stop**.
- Open the **Run** dialog box and type **services.msc**. Click **OK**. If prompted for permission to continue, click **Continue**. Then, right-click the **SQL Server (ACT7)** row. Click **Stop** or **Start**.
- Open the **SQL Server Configuration Manager** and click the **SQL Server Services** item in the left pane. In the right pane, select **SQL Server (ACT7)**. Then, on the toolbar, select the **Stop Service** or **Start Service** tool, as appropriate.

Viewing Database Information

You can view database information for all databases registered to the SQL Server instance for Sage ACT!. The Database List includes the default SQL Server system databases (master, model, msdb, and tempdb) and Sage ACT! databases. Generally, you will not need to take any action with the SQL Server system databases, but they are critical to the operation of the SQL Server instance for Sage ACT!.

The Database Grid of the Database List includes the following columns:

Column	Description
DATABASE	Physical name of the SQL Server database.
STATUS	Usually shows ONLINE. If the SQL Server cannot bring a database online (for example, when the database's ADF file has been deleted), the value is SUSPECT.
SIZE	Approximate size in megabytes (MB) of the database file (ADF).
VERSION	Schema version of the Sage ACT! database.
SYNCING	Displays information as follows: No - Database not currently set up to synchronize. N/A - Synchronization not applicable. Publisher - Database is main database. Subscriber - Database is a remote database. Publisher/Subscriber - Database is a remote subscriber that synchronizes with handheld devices.
SHARED	Indicates whether or not the database is shared.
LOCKED	Indicates a database lock is set in Sage ACT!. Displays Locked or Unlocked for a Sage ACT! database and nothing for a non-Sage ACT! database.
CREATED DATE	Date and time the database was created.
PATH	Location of the folder containing the database's ADF or MDF file.
OPTIONS	SQL Server database options currently set. For informational purposes only and may be used by Sage Technical Support.
DATASTORE ROOT	Location of the datastore (supplemental files) for the database.

View and refresh the list

1. Click **Databases**.
Use the bottom scroll bar to view all the columns.
2. Click **Refresh** to show changes.

Performing Database Maintenance and Other Operational Tasks

With ACTDiag, you can perform maintenance and other operational tasks for the databases listed in the Database List. When you are viewing the Database List, the Actions menu appears. It is from the Actions and Tools menus that you can access the commands that allow you to run various operations for a database. This section explains the available maintenance and operational tasks and how to select them.

Tip: Sage ACT! Development added the ability to perform several ACTDiag maintenance tasks by running a command line batch file without opening ACTDiag. This feature helps administrators who need to run maintenance tasks on multiple databases. For more information, see ["Running A Command Line Batch File"](#) on page 16.

Database Maintenance and Operational Tasks

ACTDiag lets you externally perform maintenance and other operational tasks on the local Sage ACT! database. The tasks are listed here in alphabetical order; not as they appear in the ACTDiag Actions and Tools menus.

Adjust ACT! Timeout Values. Adjusts how long Sage ACT! waits after attempting to execute a database command or connection before returning an error. The Timeout Property selections are:

- **DatabaseCommandTimeOut.Default.** Sets the number of seconds each query can take before timing out and generating an error. Most commands in Sage ACT! use this setting. The default is 60 seconds.
- **DatabaseConnectionTimeOut.Default.** Sets the number of seconds allowed to connect to the SQL Server instance for Sage ACT!. On a local or high-speed network, connection time is typically a second or two. You may need to increase the interval if you run on a dial-up or remote connection and begin having connection timeouts or other connection errors. The default is 30 seconds.
- **DatabaseCommandTimeOut.Long.** Sets the number of seconds process-intensive or batch-oriented commands can take before generating a timeout error. Examples are database maintenance tasks and some synchronization operations. The default is 3600 seconds.
- **SData.BigReadTimeOutMinutes.** Sets the timeout minutes from an SData™ feed. An SData™ (SageData™) feed is used for integration with other Sage products, such as accounting integration with Sage ACT! The default is 10 minutes.

Attach ACT! Database. Attaches an ACT! by Sage 2007 (9.x) through 2010 database or a Sage ACT! 2011 database, comprised of ADF and ALF files, to the local SQL Server instance for Sage ACT!. This command also lets you attach an ACT! Email database, comprised of an .MDF file. You would perform this operation if you want to attach one of those version databases to the local instance without forcing a current schema update. The Attach ACT! Database selections are:

- **Normal Attach.** Attach a database where both the ADF and ALF files are available.
- **Missing Log File.** Attach a database where the ALF file is missing.

Note: To attach a database and force a schema update to the current version, open the database using the Sage ACT! application on the local machine.

Back up Database (SQL bak file). Lets you immediately create a backup file (.BAK) for a selected database. You can specify the location for the backup file.

Change Time Zone. Allows you to change the time zone in activity records for selected user(s), using the Organizer field to determine activity ownership. This command corrects activity data whose time zone information and handling changed in ACT! 2005 (7.0.1). This command requires a Sage ACT! Administrator user logon.

Check Database. Verifies the physical structure of the database for damage. Items verified include data, indexes, and procedural objects within the database. You should use the Check Database task regularly to ensure the integrity of the database. If the task finds errors, run the Repair Database command.

Clear out Licenses. Removes all serial numbers from a selected database.

CAUTION: This action cannot be undone. Ensure you are selecting the correct database.

Clear Procedural Cache. Allows for the SQL Server query plans which currently are held in memory to be removed from cache. It forces SQL Server to base subsequent queries on current data statistics. Clear Procedural Cache is useful when performance has degraded.

CAUTION: You should only run this task if query performance has decreased unexpectedly or if you perform a large data operation (such as a large data import) and cannot stop and start the SQL Server service (or reboot the machine). The ACTDiag utility Reindex Database command also clears the cache automatically.

Collect all ACT!-related Log Files. Collects all files related to Sage ACT!, such as error logs, configuration files, and other log files. This command consolidates all files into one .zip file that can be used for troubleshooting issues with Sage ACT!. Included with the files is a manifest.txt file that records all files, with paths, included in the zip as well as error messages for those that were not included. The .zip file is named [Machinename]- ACT!Logs.zip and is placed on the desktop. The file is locked when ACTDiag is open, but you can use WinZip® to view the contents. You can e-mail the .zip file to Sage Technical Support for assistance.

Tip: You can also view the SQL Server error logs contained in the ACT!Logs.zip file. For more information, see ["Viewing SQL Server Error Logs" on page 7.](#)

Datastore Location. Allows you to select a naming method for a database's Shared Datastore. By default, when a Sage ACT! database is created as shared, a Windows Sharename is created on the local machine in the format of: \\\"Machinename\databasename-database files\". For a non-local user to access and connect to this shared database, the PAD file the user opens must specify the database machine name in the \"host=\" attribute. (You can open the PAD file in Notepad to specify the database machine name.) In some some network environments, both the PAD file and Datastore Location (as stored in the database) must be changed to reflect the TCP/IP address instead of the machine name. This may occur when a client machine cannot connect to the database machine using its machine name (i.e., cannot resolve via DNS) but can connect by using its TCP/IP address. In the IP Address box, in the Datastore Management dialog box, more than one TCP/IP address may appear. This happens when the machine has more than one network card and/or a wireless adapter. Choose the one suitable for your configuration.

Note: Many machines on a Windows network are controlled by a DHCP server and are assigned dynamic TCP/IP addresses, usually with a lease time of 30 days or so. If you choose to use the TCP/IP addressing method, you should periodically check the IP address of the machine or change the machine to have a static IP address.

Delete Database. Deletes the selected database. This option is available only if the database is listed as *SUSPECT*. A database can be marked SUSPECT for many reasons. A frequent reason is that the database files have been deleted from the file system. In this case, SQL Server still has knowledge of the database, but cannot find it. If you use the SQL Server Error Logs command and view the error logs generated by the SQL Server, you may find an indication as to why the database has been marked SUSPECT.

CAUTION: Back up the database before deleting it. See Sage ACT! Help for more information.

Delete Preferences. Deletes the local Sage ACT!Preferences files for the user currently logged on to the Windows operating system.

CAUTION: Deleting local preferences also resets the Email folder information for the local Sage ACT! email database. This may cause locally stored email messages to be lost.

Detach Database. Detaches a database from the SQL Server instance for Sage ACT!. This Detach Database task is an option to use when you want to move the database to a new location (drive and/or folder) on the current machine or to a different machine. Also, Sage Technical Support may ask you to detach a database that is experiencing errors, since opening a detached database forces a database validation process.

CAUTION: Back up the database before detaching it. See Sage ACT! Help for more information.

Downgrade from Premium. Performs a downgrade of a Premium tier database to a Pro (non-premium) tier. You would do this if you are planning to go from Sage ACT! Premium to Sage ACT! Pro. You will need your Premium database in the Pro or non-premium format for it to work with the Sage ACT! Pro application.

CAUTION: A downgrade cannot be undone. Be sure you make a backup copy of your Premium database BEFORE downgrading it.

Reindex Database. Performs a comprehensive re-index of all tables and indexes in the database. You would do this maintenance task if query performance has degraded or after a large data operation, such as Import. Also, if the database participates in synchronization and has very large data changes and long synchronization times, running Reindex Database may improve performance.

Release ACT! Memory. Specify whether or not Sage ACT! should attempt to release computer memory (RAM) to the Windows operating system at a specified interval. This option can affect overall system performance and response time. For optimal performance, set this value to zero and select the "Maintain ACT! response time..." option.

- **Value in Minutes.** Type a value (or use the up and down arrows to select a value) in minutes for releasing computer memory. This option is only available when the "Maintain ACT! response time" check box is cleared. The value must be between 1 minute and 1440 minutes (24 hours).
- **Maintain ACT! response time.** Select this option to not have the software release memory at set intervals. This option is selected by default. Clear it to have the software release memory at set intervals, and select the value in minutes.

Repair Database. Attempts to repair any physical damage or inconsistency found in the internal structure of the Sage ACT! database. If the Check Database task (or Database Maintenance, Check & Repair command in Sage ACT!ACTDiag) returns an error, run the Repair Database command.

Reset Database Preferences. Allows you to reset all, selected, or ad hoc preferences for a selected database. You can reset layout, database maintenance, password policy, duplicate checking, and scheduling and other preferences. Preferences are reset back to the default Sage ACT! settings. **Note:** Not all preferences are stored in the database. Some are stored in the Preferences files. (e.g views in separate windows, country code display, colors, calendar hours, word processor, spelling preferences, and startup database, are considered "personal" preferences regardless of database.

CAUTION: The reset cannot be undone.

Restore Database. Restores a Sage ACT! database. Options are:

- **Restore BAK file.** Restores a database to a specified location.
- **Restore BAK file As.** Restores a database with a new name and location.

Set up ACT! SQL Users. Runs the SecurityCmdLnApp used to create the specific SQL accounts (users) that Sage ACT! requires to function and allow Sage ACT! to connect to the SQL Server database. You would use this command if you manually created the ACT7 instance, or you set up the manual instance, and you only want the database and not the Sage ACT! desktop application on the computer. This command also adds stored procedures to the master database. An output file called SecurityCmdLnApp.txt is placed on the desktop that shows if the command was run successfully.

Unlock Database. Unlocks an Sage ACT! database that was locked through the Sage ACT! application. This command is useful if you cannot unlock a local database in Sage ACT!.

View Sage ACT! Integration Logs. Sage ACT! integrates with several supported applications, such as Outlook and Google. Viewing the integration logs is useful to help you troubleshoot possibly why contacts or calendars did not synchronize with Google or Outlook.

Selecting Database Maintenance and Operational Tasks

CAUTION: Several database maintenance tasks require exclusive use of the Sage ACT! database. Selecting a task disconnects (stops) all connections to the database.

Select a database maintenance or operational task

1. Click **Database**, and then click **Database List** to open the Database Grid.
2. Select the database.
3. Do one of the following depending on the type of task you want to do:
 - On the **Actions** menu, select a command.
 - On the **Tools** menu, select a command.
4. If required, at the disconnect message, click **Yes**.
5. At the task completed message, click **OK**.

Running A Command Line Batch File For Database Maintenance or Operational Tasks

If you are an Administrator and managing and deploying multiple Sage ACT! databases, you can run a command line batch file to quickly perform maintenance or other operational tasks on databases. You must create your own batch file or contact Sage ACT! Technical Support. For the command line batch file, options are explained by entering `actdiag /?` at the commandline.

General Guidelines:

The following are guidelines for creating the batch file:

- A command can be entered with or without preceding `/` or `-`. `Attach`, `/Attach`, `-Attach` are acceptable.
- The command line is not case sensitive. `Attach`, `ATTACH`, or `attach` are acceptable.

Usage

The following are uses of the database maintenance tasks you can run from a command line:

- `Attach <database name> <complete adf file path> [optional-<complete alf file path>]`- attaches database with or without log file.
- `Backup <database name>, <directory>` - backs up the database.
- `Check <database name>` - checks database for errors.
- `Delete <database name>` - deletes database. **CAUTION:** This is NOT recoverable.
- `Detach <database name>` - detaches database.
- `Downgrade <database name>` - downgrades a Premium database to a non-premium tier.
- `Flush <database name>` - flushes the procedural cache to release memory.
- `License <database name>` - purges the licenses from the selected database.
- `Reindex <database name>` - reindexes database.
- `Repair <database name>` - repairs database errors.
- `Restore <bak file to restore including path>, <directory>` - restores database placing files in specified directory folder.

- RestoreAs <database name>, <bak file to restore including path>, <directory> - restores database with new name and places the files in specified directory folder.
- ? - displays usage information.

BETA (DRAFT)

Rebuilding Databases

ACTDiag provides several database rebuild actions to help you rebuild and repair various areas of foundational Sage ACT! data, objects, and other metadata to support the Sage ACT! Framework and/or application.

In this section, you will learn about the database rebuild actions and how to select them.

Database Rebuild Actions

You can run these database rebuild actions as reactive (not proactive) corrective measures. They are generally safe to run at any time and do not offer choices or require user intervention.

Rebuild Schema. Rebuilds the representational schema metadata of the database. Schema refers to the layout of the database and allows proper and consistent viewing from Sage ACT! and other supported areas. You might run this action if errors appear indicating that a column cannot be found, or if you believe a column to be missing or showing incorrect attributes.

Rebuild Security. Rebuilds the Users and Teams tables in the database based on defined data security rules. You might run this action if data security access appears to be incorrect. For example, Sage ACT! Administrator or Manager users might not be able to view public or limited access contacts or a user has access to a field that is set to No Access.

Rebuild OLE/DB Report Objects. Rebuilds the read-only SQL Server views of the Sage ACT! database used by the earlier version of the ACT! OLE/DB Provider. You might run this action when View tables do not appear on the field list or tables do not appear to be correct. The database may be missing customized fields.

Rebuild OLE/DB v2.0 Report Objects. Rebuilds the SQL Server views of the Sage ACT! database used by the ACT! OLE DB Provider for Reporting 2.0. You might run this action when View tables do not appear on the field list or tables do not appear to be correct.

Rebuild Sync Objects. Rebuilds the synchronization logging triggers and other configuration and reporting data. This action corrects any logs or data, as required. The action also purges Sync logs and advances the Sync Log Retain Date, if possible. You might run this action if it appears that some data is not synchronizing properly or you receive error messages during synchronization. This also is useful if the Sync Log Retain Date does not appear to be resetting properly (based on normal operation and with consideration of the related database expiration days).

Remove Accounting Link IDs. Removes (deletes) all Accounting Framework Links in the database. This action removes the links to all contacts from accounting programs that were implemented using the ACT! Accounting Link (e.g., Peachtree by Sage).

Note: You must be a Sage ACT! Administrator user to perform this action. Type your Sage ACT! user name and password, if applicable, in the database logon dialog box.

Select a database rebuild action

1. Click **Database**, and then click **Database List** to open the Database Grid.
2. Do one of the following:
 - From the list, select a database. On the **Actions** menu, point to **Database Rebuild**, and then click a rebuild command.
 - Right-click the database, point to **Database Rebuild**, and then click a rebuild command.
3. Confirm the action.
4. If you are prompted to enter your Sage ACT! user name and password, do so. Click **OK**.

Specifying Database Performance Settings

The Database Settings panel contains two tabs: ACT! Settings and SQL Server Settings. These tabs let you view and configure performance behavior setting values for the Sage ACT! database and SQL Server database.

CAUTION: As with all other settings, changes made here affect all other users who connect to the database. You should read and understand the effects of each setting change and make changes only when directed by Sage Technical Support.

This section explains each tab, its default options, and tells you how to change the options.

ACT! Settings Tab Options

Each Sage ACT! database may contain configuration settings that you can modify if directed to by Sage Technical Support. The settings affect performance and product behavior or capacities. A tooltip provides acceptable Value settings.

Contact Membership Recordlimit. Sets the maximum number of group or company records to which a contact belongs. You might change this value on databases that have many group or company records that use dynamic membership (queries). Setting this value lower helps reduce the workload on the database server by stopping the search once the number of matches has been reached. The default value is 250000.

Enable OLE/DB Reporting. Enables or disables (0 = disable, 1 = enable) the generation/maintenance of the OLE/DB Reporting Views for the older version of the ACT! OLE DB Provider for Reporting v1.0. (This does not apply to the ACT! OLE DB Provider for Reporting v2.0). You might change this setting to override the join limitation with more than 75 virtual fields. By default, OLE/DB reporting is enabled (1).

Enable Procedure Tracing. Enables or disables (0 = disable, 1 = enable) the tracing of certain SQL Server procedural objects. By default, tracing is disabled (0).

Reindex Threshold. Specifies the fragmentation threshold (tolerance) value at which a table Reindex or Defrag is recommended. A greater value represents very minimal fragmentation tolerance and a lesser number represents a greater degree of acceptable fragmentation. You might decrease the value if the database is very large and takes a long time to perform reindexing. The default value is 90.

Statistics Sample Percentage. Sets the sampling size (in percent) to use when performing UPDATE STATISTICS operations for database tables and indexes. You might decrease this value by a small amount if the database is very large and takes a long time to perform checking and repairing. Increasing the value ensures that a greater amount of actual data is evaluated and considered for query plan optimization. The default value is 75.

SQL Server Settings Tab Options

This tab lets you change settings to the SQL Server database (and underlying ADF & ALF files). These settings can alter the behaviors or performance of the database.

Changes made on the SQL Server Settings tab are recorded and viewable in the Database "Audit Logs" panel under the "SQL Server Configuration - Database Configuration" Event Type. For more information, see ["Viewing and Exporting Database Audit Logs" on page 25](#).

The settings you can change are:

Auto Shrink. Determines whether or not the database files (ADF & ALF) are candidates for automatic periodic shrinking by SQL Server. If selected, this option automatically attempts to compact and reclaim unused space by the database files. The compaction task is performed in the background as necessary. However, on larger, multiuser workgroup databases with highly volatile data operations (such as large import operations or Purge History), this task may interfere with database availability. This could cause momentary delays or disruptions in connections for Sage ACT! users. If cleared, the task will only be performed when you run database maintenance tasks (and Reindex in ActDiag). The default value is selected.

Auto Close. Determines whether or not the database is shut down and resources are cleared when the last user exits. If this option is selected, the database is shut down cleanly and resources are freed. This enables the database files (ADF & ALF) to be copied when no users are logged into the database. If this option is cleared, the database remains open after the last user exits. In this mode, a user will receive a "file in use" error if the database files are attempted to be copied, moved or renamed. Also, when cleared, the SQL Server instance protects the database files from viruses or from tampering or copying by other users. The default value is cleared.

View or change a database's performance setting

1. Click **Databases**, and then click **Database Settings**.
2. From the **Database List**, select a database.
3. On the **ACT! Settings** tab, do the following:
 - a. From the **Configuration** list, select an item.

The Explanation section describes the configuration item and values you can enter.
 - b. To change the value, position the pointer in the **Value** field, type a different value.
 - c. Click **Apply**. (To cancel or undo a change, click Cancel.)
4. Click the **SQL Server Settings** tab.
 - a. Select or clear an option.
 - b. Click **Apply**. (To cancel or undo a change, click Cancel.)

Once Apply is clicked, changes are applied immediately and do not require a restart of the SQL Server instance for Sage ACT! or your operating system. Users do not need to close and re-open the database.

Running Database Reports

ACTDiag offers various reports relating to database structure, synchronization, and so on. You can use these reports for informational or troubleshooting purposes. Sage Technical Support may request that you run one or more of these reports to help resolve issues.

The following section describes the database reports and how to run and print them.

Database Structure, Synchronization, and Other Reports

All database reports open in an associated program, such as Windows Notepad or Microsoft Excel®. Using the File menu, you can save or print the report.

Fields Summary. Displays one line for each field in the selected database.

Fields Detail. Displays details, such as field attributes, for fields in the selected database. This report is more comprehensive than the Fields Summary Report.

Fields List to CSV File. Creates a comma-separated value file for the current fields in the database. Each field appears on one line and contains approximately the same level of information as the Fields Detail Report.

Company Linked Fields. Displays the linked company and contact fields in the selected database. The linked fields' attributes, such as data type and length, are also detailed in the report.

Fields Usage Analysis. Displays column usage and sizing for each table within the Sage ACT! Recordtypes (Entities) including contacts, groups, and companies. This report assists the user in identifying the database structure and patterns in data usage. From this information, the user can take actions, such as reducing column lengths or removing unused columns, to improve performance and storage requirements. The key components of this report include:

- The number and percentage (density) of records containing data in each column.
- The minimum, maximum, and average data lengths of values found in each column.
- A recommendation for each column based on the density and defined column length vs. values.

Table Row(Record)counts. Displays, by Sage ACT! Recordtype (Entity), the number of records contained in each table, either comprising the record itself and/or supporting the record. Each table is shown with the name the user sees in the application and the physical database name. In addition to Sage ACT! Entities, other database tables are shown categorized by subject area (Domain). This report helps the user understand or verify the contents of database tables.

Sync Configuration. Provides an overview of all synchronization-related configurations, metadata, and structure within the synchronization family.

Sync Preview. Provides an overview of the changes that have occurred since the last successful database synchronization. This report only lists *direct* remote (subscriber) databases as well as itself (if the current database is a remote database). The report provides totals of data by table domain and by the physical table in that domain (to assist with troubleshooting).

For troubleshooting database synchronization, use the Sync Preview Report to look for large data counts in tables and totals. If data counts are high, and your database synchronization session is timing out, you may need to extend the database timeout value in the Sync config file.

Sync Database History. Provides current and historical information for each synchronizing database. A Field Legend at the top of the report explains the columns used. This report includes the current subscriber database information and all direct subscriber databases.

Tip: You can also view the database audit logs related to database synchronization. For more information, see "[Viewing and Exporting Database Audit Logs](#)" on page 25.

Objects. Available as a Summary and Detail report. Both versions provide a high-level inventory of items in the database. These reports may help Sage Technical Support troubleshoot other database issues. The Detail Report also provides a list of every item by type (Table, Procedure, and so on). This list could be quite long and generally would only be needed if requested by Sage Technical Support to help diagnose a problem.

Missing Attachments. Helps identify broken links for attachments that display in the database. A broken link can occur for many reasons, for example, if a user has manually deleted a file in the database's supplemental Attachments folder without deleting the attachment reference (or the History item itself) in Sage ACT!. Another example of a broken link is a remote database user may delete an attachment to a contact record and when the record synchronizes to the main database, the link becomes broken. The report lists each file and indicates if it is referenced on a History, Notes, Activities, or Documents tab. If applicable, the report also indicates the synchronizing database that created the attachment.

Run a database report

1. Click **Database**, and then click **Database List** to open the Database Grid.
2. Do one of the following:
 - On the **Actions** menu, point to **Database Reports**, expand the report categories, and select a report.
 - Right-click a database, and then point to **Database Structure** or **Database Reports**. Expand the categories to select the report.
3. To view the report, at the report completed message, click **Yes**.
The report opens in Notepad or an applicable application. You can save or print it.

Viewing and Exporting Database Audit Logs

Each Sage ACT! database contains an internal Event Log that can capture many actions that occur in Sage ACT!. For example, the Database Schema - Table Definition event log captures adds, updates, and deletes for the database schema. This event is a good audit trail. It provides visibility of changes to the database schema when using the Define Fields tool in Sage ACT!.

For many actions, such as administrative tasks and actions that affect the entire database, it is often best to review those events chronologically. However, not all Event Types are logged. Some are reserved for future use. In the future, Event Types may be added or removed.

The Audit Logs command opens the panel that lets you view events by Event Type and shows:

- Who performed the action (for a system event that is not user-specific, the USER is ACT! System).
- When the event occurred.

As part of Database Maintenance, Event Log records for events over 45 days old are purged from the database. This is not configurable.

Sage Technical Support may ask you to export the Event Log records to an XML file.

View and export an audit log

1. Click **Databases**, and then click **Audit Logs**.
2. From the **Database** list, select the database.
3. In the **Event Types** field, select an event type from the list.
4. To export the log to an XML file, click **Export**.
 - a. In the **Event Log Filtering** dialog box, select a date to filter the event log by. Click **OK**.
 - b. At the **Export Audit Logs** message box, click **Yes** to save the XML file to your desktop.
 - c. To view the XML file, click **Yes**.
 - d. If necessary, limit the scope of log entries by date to help reduce the number of resulting entries and file size.

The resulting file is placed on the desktop with the name: [database_name] - Database Audit Logs.XML.
